## Multipoint Analysis for Sibling Pairs

Biostatistics 666

## Example of a Linkage Study

- In the US, age-related macular degeneration (AMD) is the most common cause of blindness in the elderly.
- Disease is heterogeneous, with two common forms of severe disease, termed "wet" and "dry" disease.
- Linkage study examined 734 genetic markers ( $\sim 1$ per 5Mb) in 412 affected relative pairs.
- Evidence for linkage to several regions, including chr1 ( $\sim 240 \mathrm{cM}$ ) and chr22 ( $\sim 25 \mathrm{cM}$ ). We now know these correspond to CFH and TIMP3 susceptibility alleles.
- American Journal of Human Genetics (2004) 74:482-494

## AMD Linkage Study,

Results of Marker by Marker Analysis

Colors: All AMD, "Wet" Subtype, "Dry" Subtype

## AMD Linkage Study,

## Results of Multipoint Analysis

chromosome 5

chromosome 22

Colors: All AMD, "Wet" Subtype, "Dry" Subtype

## Previously ...

- Linkage analysis with sibling pairs
- Risch's Maximum LOD Score approach
- Holman's Possible Triangle Constraint
- Distribution of IBD in affected sibling pairs

## Affected Sib Pair Linkage Tests

- Consider affected sibling pairs
- Pairs selected to have similar phenotypes ...
- ... show increased similarity at loci that change disease risk
- Scan the genome and test whether pair genotypes are more similar than expected ...

## Likelihood for a Single ASP

$$
L_{i}=\sum_{j=0}^{2} P(I B D=j \mid A S P) P(\text { Genotypes } \mid \text { IBD }=j)=\sum_{j=0}^{2} z_{j} w_{i j}
$$

Risch (1990) defines

$$
w_{i j}=P\left(\text { Genotypes }_{i} \mid I B D=j\right)
$$

We only need proportionate $w_{i j}$

## $w_{i j}$ for single marker analyses

| Relative |  | IBD |  |  |
| :---: | :---: | :---: | :---: | :---: |
| I | II | 0 | 1 | 2 |
| (a,b) | (c,d) | $4 \mathrm{pa}_{\mathrm{a}} \mathrm{P}_{\mathrm{b}} \mathrm{P}_{\mathrm{c}} \mathrm{P}_{\mathrm{d}}$ | 0 | 0 |
| (a,a) | (b,c) | $2 \mathrm{pa}^{2} \mathrm{P}_{\mathrm{b}} \mathrm{p}_{\mathrm{c}}$ | 0 | 0 |
| (a,a) | $(\mathrm{b}, \mathrm{b})$ | $\mathrm{Pa}^{2} \mathrm{~Pb}^{2}$ | 0 | 0 |
| (a,b) | (a,c) | $4 \mathrm{pa}^{2} \mathrm{p}_{\mathrm{b}} \mathrm{P}_{\mathrm{c}}$ | $\mathrm{PaP} \mathrm{P}_{\mathrm{b}} \mathrm{P}_{\mathrm{c}}$ | 0 |
| (a,a) | $(\mathrm{a}, \mathrm{b})$ | $2 p_{a}{ }^{3} \mathrm{P}_{\mathrm{b}}$ | $\mathrm{Pa}^{2}{ }^{2} \mathrm{~Pb}$ | 0 |
| (a,b) | $(\mathrm{a}, \mathrm{b})$ | $4 \mathrm{pa}^{2} \mathrm{p}_{\mathrm{b}}{ }^{2}$ | $\left(\mathrm{paPb}^{2}+\mathrm{p}^{2}{ }^{2} \mathrm{~Pb}\right)$ | $2 \mathrm{pap}_{\mathrm{b}}$ |
| (a,a) | (a,a) | $\mathrm{pa}^{4}$ | $\mathrm{Pa}^{3}$ | $\mathrm{pa}^{2}$ |

| Prior Probability | $1 / 4$ | $1 / 2$ | $1 / 4$ |
| :--- | :--- | :--- | :--- |

These probabilities apply to pair of individuals, when no other genotypes in the family are known.

## MLS Linkage Test

$$
\begin{aligned}
& L\left(z_{0}, z_{1}, z_{2}\right)=\prod_{i} \sum_{j} z_{j} w_{i j} \\
& L O D=\log _{10} \prod_{i} \frac{z_{0} w_{i 0}+z_{1} w_{i 1}+z_{2} w_{i 2}}{1 / 4 w_{i 0}+1 / 2 w_{i 1}+1 / 4 w_{i 2}}
\end{aligned}
$$

The MLS statistic is the LOD evaluated at the MLEs of $\mathrm{z}_{0}, \mathrm{z}_{1}, \mathrm{z}_{2}$
These MLEs can be calculated using an EM algorithm

## P(Affected Pair |IBD=j)

$\begin{aligned} P(\text { Affected Pair } \mid \text { IBD }=0) & =\left(p^{2} f_{11}+2 p(1-p) f_{12}+(1-p)^{2} f_{22}\right)^{2} \\ & =K^{2}\end{aligned}$
$P($ Affected Pair $\mid \operatorname{IBD}=1)=p^{3} f_{11}^{2}+2 p^{2}(1-p) f_{11} f_{12}+p(1-p) f_{12}^{2}$

$$
=\lambda_{o} K^{2}+2 p(1-p)^{2} f_{12} f_{22}+(1-p)^{3} f_{22}^{2}
$$

$P($ Affected Pair $\mid$ IBD $=2)=p^{2} f_{11}^{2}+2 p(1-p) f_{12}^{2}+(1-p)^{2} f_{22}^{2}$
$=\lambda_{M Z} K^{2}$

## P(Affected Sibling Pair), P(IBD = j|Affected Sibling Pair)

$$
\begin{aligned}
& P(A S P)=\sum \mathrm{P}(I B D=\mathrm{i}) \mathrm{P}(\mathrm{ASP} \mid I B D=\mathrm{i})=\left(1 / 4+1 / 2 \lambda_{0}+1 / 4 \lambda_{M Z}\right) K^{2}=\lambda_{s i b} K^{2} \\
& P(I B D=j \mid A S P)=\frac{P(I B D=j) P(A S P \mid I B D=j)}{P(A S P)} \\
& P(I B D=0 \mid A S P)=0.25 \frac{1}{\lambda_{s i b}} \\
& P(I B D=1 \mid A S P)=0.50 \frac{\lambda_{0}}{\lambda_{s i b}} \\
& P(I B D=1 \mid A S P)=0.25 \frac{\lambda_{M Z}}{\lambda_{s i b}} \\
& 1 \leq \lambda_{0} \leq \lambda_{s i b} \leq \lambda_{M Z}
\end{aligned}
$$

## Possible Triangle Constraint

## Important Limitation

- A major limitation of our approach so far is that it considers one marker at a time

This may not allow us to extract all available information about IBD...

## Today ...

- Refresher on IBD probabilities
- Intuition behind multipoint calculations
- Framework for multipoint calculations
- Using a Markov Chain to speed analyses

## IBD Probabilities

- Number of alleles identical by descent
- For sibling pairs, must be:
${ }^{-} 0$
- 1
${ }^{-} 2$

Often, remains ambiguous given genotype

## Refresher ... <br> Bayes Theorem for IBD Probabilities

$$
\begin{aligned}
P(I B D=i \mid X) & =\frac{\mathrm{P}(\mathrm{IBD}=i, X)}{P(X)} \\
& =\frac{P(I B D=i) P(X \mid I B D=i)}{P(X)} \\
& =\frac{P(I B D=i) P(X \mid I B D=i)}{\sum_{j} P(I B D=j) P(X \mid I B D=j)}
\end{aligned}
$$

$$
p_{1}=0.5
$$

## Worked Example

$$
\begin{array}{ll}
\hline 1 / 1 & 1 / 1 \\
\hline
\end{array}
$$

$$
\begin{aligned}
& P(X \mid I B D=0)=p_{1}^{4}=1 / 16 \\
& P(X \mid I B D=1)=p_{1}^{3}=1 / 8 \\
& P(X \mid I B D=2)=p_{1}^{2}=1 / 4 \\
& P(X)=1 / 4 p_{1}^{4}+1 / 2 p_{1}^{3}+1 / 4 p_{1}^{2}=9 / 64 \\
& P(I B D=0 \mid X)=\frac{1 / 4 p_{1}^{4}}{P(X)}=1 / 9 \\
& P(I B D=1 \mid X)=\frac{1 / 2 p_{1}^{3}}{P(X)}=4 / 9 \\
& P(I B D=2 \mid X)=\frac{1 / 4 p_{1}^{2}}{P(X)}=4 / 9
\end{aligned}
$$

## Intuition For Multipoint Analysis

- IBD changes infrequently along the chromosome
- Neighboring markers can help resolve ambiguities about IBD sharing
- In the Risch approach, they might ensure that only one w is effectively non-zero

## Ingredients for Multipoint Model

- Probability of observed genotypes at each marker conditional on IBD state
- Probability of changes in IBD state along chromosome
- Hidden Markov Model

## Ingredients

One ingredient will be the observed genotypes at each marker ...

## Ingredients

Another ingredient will be the possible IBD states at each marker ...

## Ingredients

The final ingredient connects IBD states along the chromosome ...

## The Likelihood of Marker Data

$L=\sum_{I_{1}} \sum_{I_{2}} \cdots \sum_{I_{M}} P\left(I_{1}\right) \prod_{i=2}^{M} P\left(I_{i} \mid I_{i-1}\right) \prod_{i=1}^{M} P\left(X_{i} \mid I_{i}\right)$

- General formulation, allows for any number of markers.
- Combined with Bayes' Theorem can estimate probability of each IBD state at any marker.
- This is not a linkage test yet!

## $P\left(X_{m} \mid I_{m}\right)$

| Sib | CoSib | IBD |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | 1 | 2 |
| (a,b) | (c,d) | $4 \mathrm{pa}_{\mathrm{a}} \mathrm{P}_{\mathrm{b}} \mathrm{P}_{\mathrm{c}} \mathrm{Pd}_{\mathrm{d}}$ | 0 | 0 |
| (a,a) | (b,c) | $2 \mathrm{pa}^{2}{ }_{2} \mathrm{p}_{\mathrm{b}} \mathrm{p}_{\mathrm{c}}$ | 0 | 0 |
| (a,a) | (b,b) | $\mathrm{pa}^{2} \mathrm{p}_{\mathrm{b}}{ }^{2}$ | 0 | 0 |
| (a,b) | ( $\mathrm{a}, \mathrm{c}$ ) | $4 \mathrm{pa}^{2}{ }^{2} \mathrm{p}_{\mathrm{b}} \mathrm{p}_{\mathrm{c}}$ | $\mathrm{pap}_{\mathrm{a}} \mathrm{p}_{\mathrm{b}} \mathrm{P}_{\mathrm{c}}$ | 0 |
| (a,a) | (a,b) | $2 \mathrm{pa}^{3} \mathrm{p}_{\mathrm{b}}$ |  | 0 |
| (a,b) | (a,b) | $4 \mathrm{pa}^{2} \mathrm{p}_{4}{ }^{2}$ | $\left(\mathrm{pap}_{\mathrm{b}}{ }^{2}+\mathrm{p}_{\mathrm{a}}{ }^{2} \mathrm{p}_{\mathrm{b}}\right)$ | $2 \mathrm{pap}_{\mathrm{a}} \mathrm{p}_{\mathrm{b}}$ |
| (a,a) | ( $\mathrm{a}, \mathrm{a}$ ) | $\mathrm{Pa}^{4}$ | $\mathrm{Pa}^{3}$ | $\mathrm{pa}^{2}$ |
| Prior | bability | $1 / 4$ | 1/2 | 1/4 |

## Question: <br> What to do about missing data?

- What happens when some genotype data is unavailable?

## $P\left(I_{m+1} \mid I_{m}\right)$

- Depends on recombination fraction $\theta$
- This is a measure of distance between two loci
- Probability grand-parental origin of alleles changes between loci
- Leads to probability of a change in IBD:

$$
\psi=2 \theta(1-\theta)
$$

## $P\left(I_{m+1} \mid I_{m}\right)$

|  |  | IBD State at $\mathrm{m}+1$ |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | 1 | 2 |
| IBD state | 0 | $(1-\psi)^{2}$ | $2 \psi(1-\psi)$ | $\psi^{2}$ |
| at marker | 1 | $\psi(1-\psi)$ | $(1-\psi)^{2}+\psi^{2}$ | $\psi(1-\psi)$ |
| m | 2 | $\psi^{2}$ | $2 \psi(1-\psi)$ | $(1-\psi)^{2}$ |

$$
\psi=2 \theta(1-\theta)
$$

## Example

- Consider two loci separated by $\theta=0.1$
- Each loci has two alleles, each with frequency . 50
- If two siblings are homozygous for the first allele at both loci, what is the probability that IBD $=2$ at the first locus?

## The Likelihood of Marker Data

$L=\sum_{I_{1}} \sum_{I_{2}} \cdots \sum_{I_{M}} P\left(I_{1}\right) \prod_{i=2}^{M} P\left(I_{i} \mid I_{i-1}\right) \prod_{i=1}^{M} P\left(X_{i} \mid I_{i}\right)$

- General, but slow unless there are only a few markers.
- How do we speed things up?

## A Markov Model

- Re-organize the computation slightly, to avoid evaluating nested sum directly
- Three components:
- Probability considering a single location
- Probability including left flanking markers
- Probability including right flanking markers
- Scale of computation increases linearly with number of markers

## The Likelihood of Marker Data

$$
\begin{aligned}
L & =\sum_{I_{j}} P\left(I_{j}\right) P\left(X_{j} \mid I_{j}\right) P\left(X_{1} \ldots X_{j-1} \mid I_{j}\right) P\left(X_{j+1} \ldots X_{M} \mid I_{j}\right) \\
& =\sum_{I_{j}} P\left(I_{j}\right) P\left(X_{j} \mid I_{j}\right) L_{j}\left(I_{j}\right) R_{j}\left(I_{j}\right)
\end{aligned}
$$

- A different arrangement of the same likelihood
- The nested summations are now hidden inside the $L_{j}$ and $R_{j}$ functions...

## Left-Chain Probabilities

$$
\begin{aligned}
L_{m}\left(I_{m}\right) & =P\left(X_{1}, \ldots, X_{m-1} \mid I_{m}\right) \\
& =\sum_{I_{m-1}} L_{m-1}\left(I_{m-1}\right) P\left(X_{m-1} \mid I_{m-1}\right) P\left(I_{m-1} \mid I_{m}\right) \\
L_{1}\left(I_{1}\right) & =1
\end{aligned}
$$

- Proceed one marker at a time.
- Computation cost increases linearly with number of markers.

## Right-Chain Probabilities

$$
\begin{aligned}
R_{m}\left(I_{m}\right) & =P\left(X_{m+1}, \ldots, X_{M} \mid I_{m}\right) \\
& =\sum_{I_{m+1}} R_{m+1}\left(I_{m+1}\right) P\left(X_{m+1} \mid I_{m+1}\right) P\left(I_{m+1} \mid I_{m}\right)
\end{aligned}
$$

$$
R_{M}\left(I_{M}\right)=1
$$

- Proceed one marker at a time.
- Computation cost increases linearly with number of markers.

## Pictorial Representation

- Single Marker
- Left Conditional

- Right Conditional
- Fullikelihood

## Extending the MLS Method ...

$$
\begin{aligned}
w_{j} & =P\left(X_{j} \mid I_{j}\right) P\left(X_{1} \ldots X_{j-1} \mid I_{j}\right) P\left(X_{j+1} \ldots X_{M} \mid I_{j}\right) \\
& =P\left(X_{j} \mid I_{j}\right) L_{j}\left(I_{j}\right) R_{j}\left(I_{j}\right)
\end{aligned}
$$

- We just change the definition for the "weights" given to each configuration!

## Possible Further Extensions

- Modeling error
- What components might have to change?
- Modeling other types of relatives
- What components might have to change?
- Modeling larger pedigrees
- What components might have to change?

## Today

- Efficient computational framework for multipoint analysis of sibling pairs
